

Witenbergitaenia sinaica gen. n., sp. n. (Anoplocephalidae) and other Cestodes from small Mammals in Israel and in the Sinai Peninsula

by Guta WERTHEIM, Gerald D. SCHMIDT and Zalman GREENBERG

Abstract. — Twelve species of Cestodes are reported from twenty species of small mammals recovered in Israel and Sinai. Eight other adult Cestodes were identified to genus only. New host and locality records are indicated in table 1 and in the text. *Witenbergitaenia sinaica* gen. n., sp. n., found in *Acomys cahirinus* in southern Sinai, differs from *Markewitchitaenia* and *Tupaiataenia*, the only other genera in Anoplocephalidae with a hermaphroditic canal, in having two postovarian fields of testes.

Résumé. — *Witenbergitaenia sinaica* n. g., n. sp. (Anoplocephalidae) et autres Cestodes parasites de petits Mammifères d'Israël et de la péninsule du Sinaï. — Douze espèces de Cestodes ont été trouvées chez vingt espèces de petits mammifères récoltés en Israël et dans la péninsule du Sinaï. Huit autres Cestodes adultes ont été identifiés seulement jusqu'au niveau générique. Les nouveaux hôtes et les nouvelles localités sont indiqués dans le tableau 1 et dans le texte. *Witenbergitaenia sinaica* n. g., n. sp., récoltée chez *Acomys cahirinus* dans le sud du Sinaï, diffère de *Markewitchitaenia* et de *Tupaiataenia*, les seuls autres genres d'Anoplocephalidae possédant un canal hermaphrodite, par la présence de deux champs de testicules postovariens.

INTRODUCTION

In a previous publication (SCHMIDT, GREENBERG and WERTHEIM, 1986) survey data on avian Cestodes were reported as well as information on collection sites and techniques used in processing and mounting the specimens. The present communication deals with Cestodes recovered from small mammals, mostly rodents.

The earliest findings on Cestodes, published with the initiation of helminthological studies in Israel (then Palestine), dealt with the fauna of domestic and wild carnivores possibly because of the importance of these animals as a source of human infections. In stray dogs and cats, WITENBERG (1932, 1933, 1934a, b) found five species of Dilepidinae, one species of Mesocestoididae (genus *Mesocestoides*) and five species of Taeniidae, among them *Echi-*

nococcus granulosus (recorded also from the jackal *Canis aureus*). From the presence of some of these taeniids one could infer that their larval forms will be found in rodents or other small mammals. This was later proven when extensive studies of these animals were undertaken. Cysticercus of *T. taeniaeformis*, for example, was reported from rats (WERTHEIM, 1963) and from *Nesokia indica*, Rodentia-Muridae (GREENBERG, 1972). Other cestodes from rodents, so far reported include *Megittina gerbilli*, *Hymenolepis dinninuta* and *Vampirolepis nana* (WERTHEIM, 1954, 1963). *Vampirolepis negevi* (= *Rodentolepis negevi*), *Pseudandrya monardi* and *Mathevotaenia symmetrica* (reported as *M. rodentinum*) (GREENBERG, 1969); *Sinaiotaenia witenbergi* (WERTHEIM and GREENBERG, 1971) and *Paranoplocephala* sp. (WERTHEIM and NEVO, 1971).

The present paper summarizes findings from examination of over two thousand small mammals as well as new host and locality records. All locality records from Sinai are new. In the data on four species of Cestodes from rodents in Sinai presented in a previous report (WERTHEIM and GREENBERG, 1970) only the hosts are listed.

RESULTS

Cestodes identified in this study, as well as data on hosts and localities, are summarized in table 1. Classification follows SCHMIDT (1986). Measurements are in micrometers unless otherwise stated. The letter n indicates the number of measurements made. One species is recognized as new and as representing a new genus. We place it within the Linstowiinae because the eggs lack a pyriform apparatus and there is only one egg per capsule.

DESCRIPTION

WITENBERGITAENIA gen. n.

DIAGNOSIS : Anoplocephalidae, Linstowiinae. Dorsoventrally flattened, becoming wider evenly toward the gravid segments. Immature segments wider than long, mature segments about as long as wide, gravid segments longer than wide. Scolex lacking rostellum, hooks or apical organ. Suckers round, powerful, unarmed. Neck present, narrower than scolex. Proglottids numerous, slightly craspedote. Osmoregulatory canals reticulated throughout proglottid. This canal system is identical with that described for *Atriotaenia procyonis* (Chandler, 1942), by GALLATI (1959), to which the reader is referred. Muscle bundles feebly developed. One set of reproductive organs per segment; genital pores irregularly alternating. Genital atrium well developed, lacking sphincter muscles, smaller than cirrus pouch. Genital ducts dorsal to osmoregulatory canals. Testes in two lateral fields, mainly postovarian, some lateral to ovary, between outer limits of osmoregulatory canals. Cirrus pouch elongate, crossing outermost osmoregulatory canals, usually reaching poral edge of ovary. Cirrus absent. Internal and external seminal vesicles absent. Ovary median, with bilateral wings subdivided into slender lobes. Vitellarium with small lobes, posterior to ovary. Vagina posterior to cirrus pouch. Distal end of vagina entering, with cirrus pouch, into common hermaphroditic canal that enters genital atrium. Seminal receptacle small, remaining discrete in gravid segments. Uterus deve-

lops as a thin-walled, reticular sac, which quickly fills and disappears, leaving abundant developing eggs evenly scattered throughout the medullary parenchyma. Oncospheres each surrounded by a single, thin-walled membrane ; pyriform apparatus absent.

TYPE SPECIES : *Witenbergitaenia sinaica* sp. n.

***Witenbergitaenia sinaica* sp. n.**

(Fig. 1, A to D)

MATERIAL STUDIED : One specimen found in 1 out of 152 host-animals examined.

DESCRIPTION

With the characters of the genus, as described above. Scolex (fig. 1A) about 480 long (measured to posterior constriction of scolex), 640 greatest width. Suckers round, 175 to 200 wide. Neck narrower than scolex, about 1.0 mm long. Strobila 71 mm long (although as much as one-fourth may be missing in the prepared slide), about 1.5 mm wide in mature portion, 2.0 mm wide in gravid segments. Proglottids slightly craspedote, anapolytic. Male and female gonads (fig. 1B) mature at same time. Genital ducts dorsal to osmoregulatory canals (fig. 1C).

Male genitalia : 41 to 62 testes ($n = 7$) in two fields of 23 to 29 (poral) and 18 to 33 (aporal), mainly posterior to ovary. Testes ($n = 23$) 60 to 100 wide in mature segments. Cirrus pouch (fig. 1C) ($n = 7$) elongate, narrowed proximally, usually reaching but not exceeding poral margin of ovary, 240 to 270 long, 60 greatest width. Internal and external seminal vesicles absent. Ejaculatory duct and vas deferens coiled. Cirrus absent.

Female genitalia : Ovary median, with bilateral wings subdivided into lobules ; not reaching main lateral osmoregulatory canals ; maximum size ($n = 7$) 345 to 480 long, 560 to 680 wide. Vitellarium ($n = 7$) posterior to ovary, lobated, 160 to 200 long, 175 to 255 greatest width. Vagina posterior to cirrus pouch, unarmed, proceeding directly to seminal receptacle, which lies between ovary and vitellarium. Seminal receptacle ($n = 7$) a simple sac 120 to 140 long, 60 to 90 wide in mature segments, slender with a single loop in gravid segments. Distal end of vagina joins hermaphroditic duct with cirrus pouch before opening into genital atrium. Atrium ($n = 7$) 70 deep, 20 to 30 wide at distal end, 10 wide at base, not exceptionally muscular or glandular. Eggs (fig. 1D) surrounded by single membrane, 54 to 64 wide ($n = 10$). Oncospheres 30 to 40 wide ; oncosphere hooks 14 to 16 long.

TYPE HOST : Egyptian spiny mouse, *Acomys cahirinus*¹ Desm., 1819. Rodentia, Muridae.

LOCATION : Small intestine.

LOCALITY : Wadi Atzvira (Southern Sinai).

TYPE SPECIMEN : MNHN (Muséum national d'Histoire naturelle, Paris) holotype n° 641 HB.

ETYMOLOGY : The genus is named in honor of the late Professor George WITENBERG, who pioneered in helminthology in Israel.

1. In a previous publication (WERTHEIM and GREENBERG, 1970) the *Acomys* from Sinai was temporarily named *A. dimidiatus*. Professor WAHRMAN informs us (personal communication) that at a later date, it was chosen, for the time being, to use the name *A. cahirinus* for all the chromosomal forms.

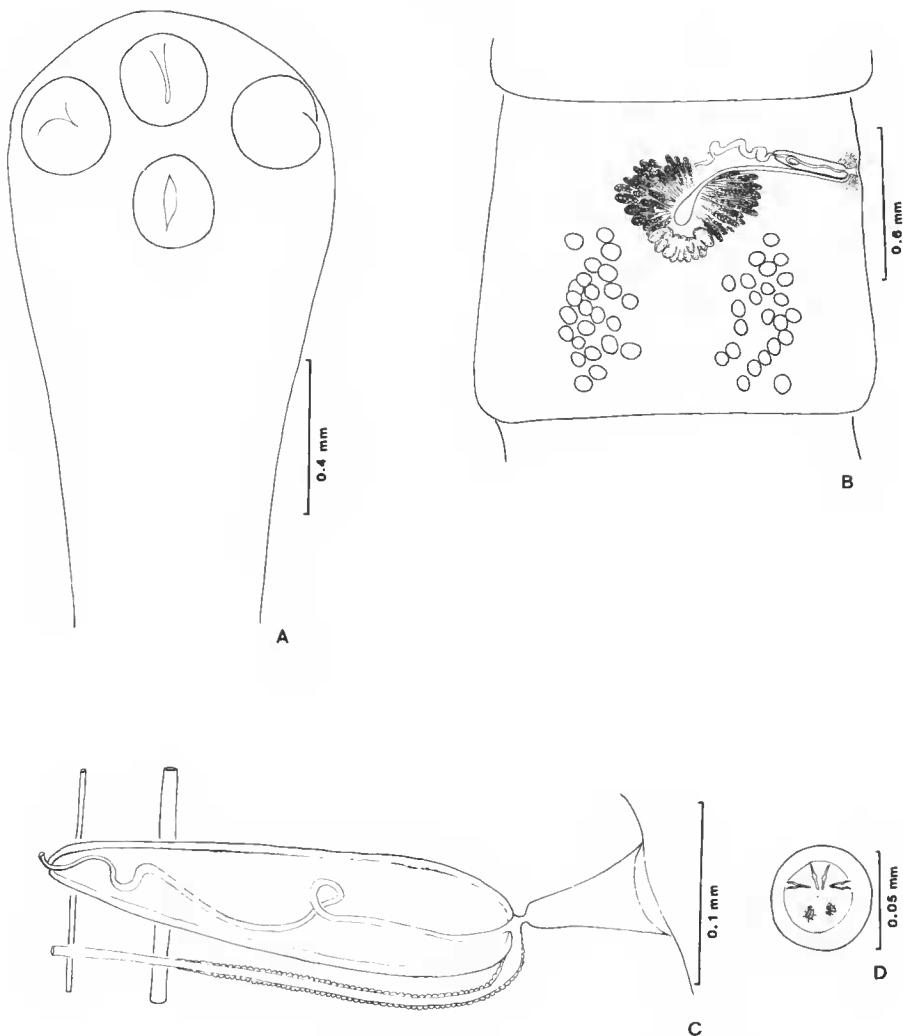

FIG. 1. — *Witenbergitaenia sinaica* sp. n. from *Acomys cahirinus* : A, scolex ; B, mature proglottid ; C, terminal genital ducts ; D, egg.

DISCUSSION

To date there are two genera in the anoplocephalid subfamily Linstowiinae with a common hermaphroditic canal as in the present species : *Markewitchitaenia* Sharpilo and Kornyushin, 1975, and *Tupaiataenia* Schmidt and File, 1975. *Tupaiataenia*, from tree shrews, is unique in possessing a cirrus and muscular lappets on the suckers.

The present species is most similar to *Markewitchitaenia* but clearly differs from it in having two lateral fields of large testes, instead of a single field of small testes.

Because the presence of two fields of testes versus one field has traditionally been accepted as a generic character (as in *Kowalewskiella*, *Schizorchis*, *Cycloskrjabinia*, *Laterotaenia* and many others) we propose our new species to represent a new genus and name it *Witenbergitaenia*.

In order to show that *W. sinaica* is not a deviant *M. rodentinum* (Joyeux, 1927) — the only species in *Markewitchitaenia* — the following comparisons are given : (1) the gravid strobila of *M. rodentinum* is about 44 mm long by 710 μm greatest width, compared with at least 70 mm long by 2.0 mm greatest width in *W. sinaica*; (2) the cirrus pouch of *M. rodentinum* is 137 to 154 μm long by 33 to 38 μm wide and reaches the midline level of the ovary, while that of *W. sinaica* is 240 μm long by 64 μm wide and barely reaches the poral edge of the ovary; (3) the total number of testes is 33 to 47 (usually 38 to 40) in *M. rodentinum*, compared with 41 to 62 in *W. sinaica*. Thus it is clear that two different species are represented.

Acknowledgments

The authors wish to express their gratitude to Pr Y. SCHLEIN, Department of Parasitology, The Hebrew University-Hadassah Medical School, for his help in collecting the animals. Thanks are due to Mrs Hermina ZYLBERMAN, Mrs Simona RADAI, Mr M. MUALLEM and Mr Y. GATTAS for technical assistance.

G.W., on sabbatical leave from the Hebrew University, wishes to express her appreciation to the Department of Biological Sciences, University of Northern Colorado, for its cooperation and hospitality during the period of this research.
